#### Abstract

Chiral synthesis of the necic base, heliotridane has been achieved by employing a samarium diiodide-promoted regioselective carbon-carbon bond cleavage reaction of the $\gamma$-halo ester (17), as a key step.

Recently we developed samarium(II) diiodide-promoted carbon-carbon bond cleavage reaction of $\gamma$-halo carbonyl compounds ${ }^{1}$ and this novel fragmentation reaction was expected to have broad utility in the synthesis of natural products. In the continuation of a research program to exploit this synthetic strategy in the natural products synthesis, 2,3 we planned the synthesis of pyrrolizidine alkaloids, and here report a chiral synthesis of the necic base, heliotridane (1), in natural enantiomeric form, together with a stereoselective synthesis of pseudoheliotridane (2).

1

2

First we investigated the synthesis of (-)-pseudo-heliotridane (2) starting from the ester (4), ${ }^{2}$ readily obtained from ( - -carvone, via the $\gamma$-halo ester (3) utilizing a regioselective fragmentation reaction as a key step, as follows.
Removal of triethylsilyl group of 4 in acetic acid-water-THF (3:1:1) afforded the alcohol (5) in quantitative yield, which on treatment with diphenylphosphoryl azide according to the Lal's procedure ${ }^{4}$ provided the azide (6) with the desired stereochemistry in $77.2 \%$ yield. Reduction of 6 with magnesium powder in methanol ${ }^{5}$ for 3 h at $0^{\circ} \mathrm{C}$ proceeded smoothly to give the lactam (7) in $94.3 \%$ yield. In order to synthesize a bicyclic ring system, the olefinic lactam (7) was subjected to ozonolysis to afford the aldehyde (8) in quantitative yield. Wittig reaction of the aldehyde (8) using methoxymethylriphenylphosphonium chloride and $n$-butyllithium provided the enol ether (9) as a mixture of $E / Z$ ( $c a .1: 1$ ratio) stereoisomers, which on treatment with aqueous acetic acid gave the cyclized product (10) as a single stereoisomer, in $24.3 \%$ yield from 8 . Although the
stereochemistry of the hydroxyl group of 10 could not be determined at this stage, we used this compound for further conversion into 11, since this stereogenic center would be removed in the next step of this synthesis.

Reduction of $\mathbf{1 0}$ with triethylsilane in trifluoroacetic acid furnished the bicyclic lactam (11), $\left\{[\alpha]_{\mathrm{D}}-63.5^{\circ}\right.$ $\left(\mathrm{CHCl}_{3}\right)$, lit., ${ }^{6}[\alpha]_{\mathrm{D}}-43.8^{\circ}\left(\mathrm{CHCl}_{3}\right)$ ), in $56.9 \%$ yield, whose spectroscopic data including specific optical

rotation were similar to those reported. ${ }^{6}$ Since this lactam was already converted into pseudo-heliotridane, 7,8 this synthesis constitutes its chiral synthesis. Establishing the synthetic procedure for pyrrolizidine ring system from carvone as above, we next attempted the synthesis of the simplest pyrrolizidine alkaloid, ( - )-heliotridane. The acid (12), ${ }^{2}$ easily prepared from ( + )-carvone, was converted into the isopropyl ester (13), which was converted to the alcohol (15) with the inversion of the configuration under the Mitsunobu reaction conditions 9 employing benzoic acid, triphenylphosphine and diethyl azodicarboxylate, followed by alkaline hydrolysis of the resulting benzoate (14), in $83.5 \%$ overall yield from 13. Addition of hydrogen chloride to the ester (15) and subsequent protection of the hydroxyl group of 16 with triethylsilyl chloride afforded the chloride (17) in $92.4 \%$ yield in two steps. Samarium(II) diiodide-promoted fragmentation of 17 provided the olefinic ester (18)

in $91.7 \%$ yield. Removal of triethylsilyl group of 18 in acetic acid-water-THF (3:1:1) gave the alcohol (19), which on treatment with diphenylphosphoryl azide using the Lal's reaction conditions furnished the azide (20) in $57.7 \%$ yield from 18. When the methyl ester (21) was employed in the above reaction, the lactone formation occurred very fast to give the $\gamma$-lactone (22). ${ }^{2}$ Transformation of the azide (20) into ( - )-heliotridane was achieved using the similar reaction conditions as described for the synthesis of $(-)$-pseudo-heliotridane as

above. Thus, the azide (20) was reduced with magnesium powder in methanol ${ }^{6}$ to give the lactam (23), whose ozonolysis, and subsequent Wittig reaction of the aldehyde (24) afforded the enol ether (25)( $E / Z=1: 1)$. Acid treatment of $\mathbf{2 5}$, followed by reduction of the resulting aminal (26), a single stereoisomer, with triethylsilane in trifluoroacetic acid yielded the lactam (27), $\left\{[\alpha] \mathrm{D}-57.63^{\circ}\left(\mathrm{CHCl}_{3}\right)\right.$, lit., $\left.6^{6}[\alpha] \mathrm{D}-52.4^{\circ}\left(\mathrm{CHCl}_{3}\right)\right\}$, whose spectroscopic data including specific optical rotation supported its structure. Since this lactam (27) was already converted into (-)-heliotridane (1), 7,8 this synthesis also constitutes its formal chiral synthesis.

Thus, we could achieve the chiral synthesis of (-)-heliotridane and ( - )-pseudo-heliotridane starting from carvone by utilizing a samarium(II)-promoted carbon-carbon bond cleavage reaction as a key step, and the synthetic strategy developed here would be applicable to the synthesis of other types of pyrrolizidine alkaloids.
